Forward

This Dekedal Hydro Meteorological Bulletin is prepared and disseminated by the Ethiopia Meteorological institute (EMI). The ultimate objective of producing and disseminating this bulletin is to inform all level decision makers with the updated and relevant hydro meteorological information. This Dekedal Bulletin reviews the December 01-10, 2025-month climate condition and its impacts over the river catchment across the country and highlights the December 11-20, 2025 climate outlook along with the likely impact over the water dams and the rivers basins.

The information contained in this bulletin is believed to assist the water professionals for planning the capacity expansion of reservoirs, water supply, ecosystem restoration as well as rehabilitation of existing systems including dams, irrigation, canals, pumps, wetlands and the likes. In addition to the aforementioned benefit the bulletin also reveals the aridity levels of each basin, extremes heavy rainfall events and areas where significant amount of moistures loss through evapotranspiration. In the impact outlook section of the bulletin it provides the likelihood of the climate in the coming month and its potential impact over various aspect of the river basins including the hydraulic structures such as culverts, bridges, reservoir spillways, road embankments and dikes. It also indicates the measures need to be taken as the early actions so as to reduce the possible negative impact of the upcoming month climate condition. Meanwhile, your comments and constructive suggestions are highly appreciated to make the objectives of this bulletin a success.

1. Introduction

The provision of hydro meteorological services can contribute a significant role toward water resource management and socio-economic development. Both surface water and groundwater management are essentially linked to climate variability. Therefore, the provided climate information and knowledge in this monthly hydro meteorological bulletin have a critical importance for efficient, equitable and sustainable development and management of the national water resources and for coping with any climate related risks. The information illustrates the impact of previous month climate on each and every water basins and the associated climate risks observed during the month under review. In addition to the previous month impact assessment, the bulletin also provided the expected climate condition for the coming months and its impact on the water resource. The design of water-use and flood-control facilities, mainly dams and reservoirs, is frequently based on these analyses. Estimating the likelihood of precipitation, the distribution of precipitation and the rate of evaporation in location and time, the heavy rainfall and the subsequent runoff, extreme temperature and wind are among issues that hydro meteorologists are concerned with.

1.1 Hydro-Meteorological Impact Assessment (December 01-10, 2025)

During the first dekad of December, most river catchments across the country were characterized by predominantly arid moisture conditions. In particular, the Afar-Danakil, Awash, Wabi-Shebelle, Genale-Dawa, Tekeze, and Aysha catchments largely remained under arid conditions throughout the period. Analysis of hydro-meteorological data indicates that these conditions exerted adverse impacts on water resources, as evidenced by the continuous decline in reservoir storage levels and a noticeable reduction in surface water flows in rivers and streams. Such conditions may have implications for water supply, irrigation, hydropower generation, and other water-dependent sectors. In contrast, limited areas of the Upper Baro-Akobo and Lower Abay catchments experienced moderate surface water flow, reflecting relatively better moisture availability compared to the rest of the country during the same period.

1.2 Hydro-Meteorological Impact Outlook (December 11-20, 2025)

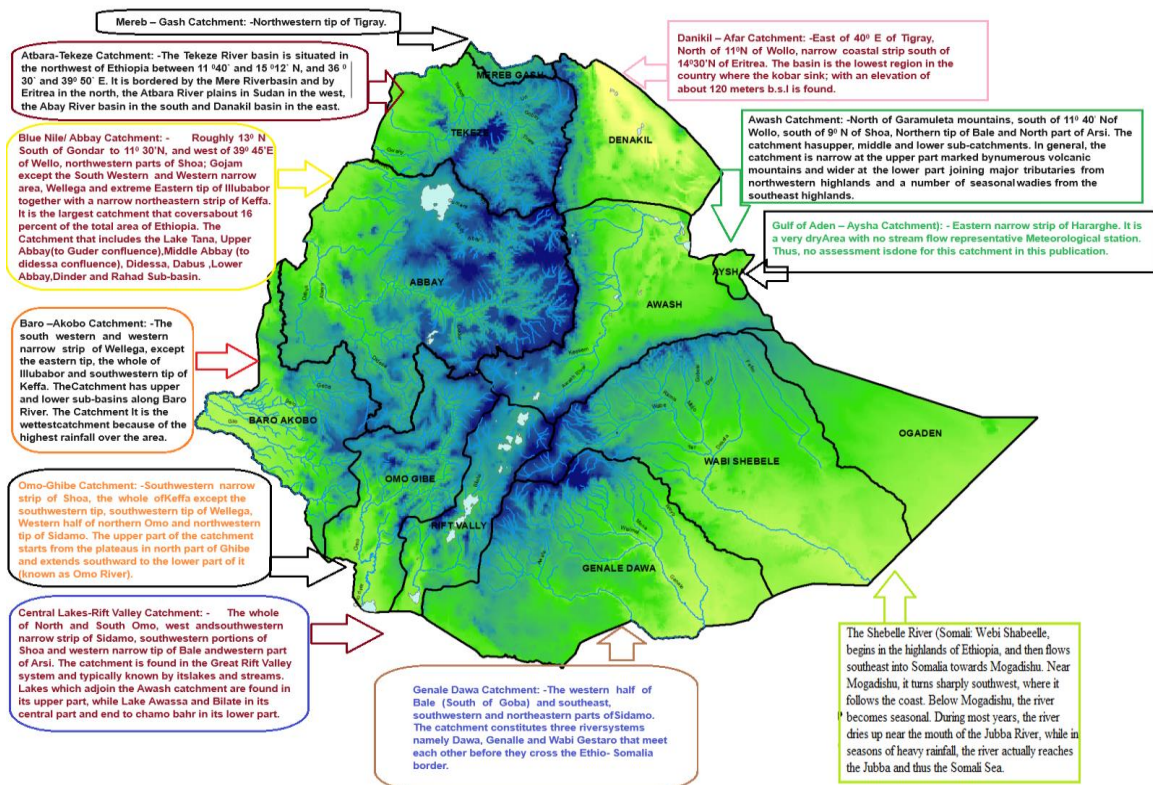

During the upcoming second dekad of December, moderate surface water flow is expected in a few river catchments, including the Upper Baro-Akobo, Middle Omo-Gibe, parts of the Middle and Lower Abay, the Middle Rift Valley, parts of the Upper Awash, and the Upper Genale-Dawa, while most other catchments across the country are likely to remain under moderately dry to dry conditions. These conditions are expected to reduce flood and sediment-related risks and ensure relatively clean river systems; however, they may also lead to decreased river flows, reduced reservoir storage, increased evapotranspiration, and potential impacts on drinking water supply, irrigation, hydropower generation, and other water-related services. In light of these conditions, concerned sectoral institutions are strongly advised to implement basin-specific hydro-meteorological advisories, including efficient use and proper harvesting of available water, rainwater collection from rooftops and ground surfaces, protection of water resources from wastage and pollution, and appropriate measures to safeguard livestock and other vulnerable sectors, in order to minimize potential adverse impacts.
